

Save Money with Clean Heat Cut Cost, Cut Carbon, Cut Complexity

How to cut carbon emissions from MA houses to net zero by 2050

Saves average homeowner \$2,500 a year
No tax increases

By adding insulation, heat pumps (to replace AC units keeping the furnace as a back up) and solar panels, most of which is paid for by the Inflation Reduction or MA law, leaving the gas network in place, just using it very little.

This is a draft for discussion and for gathering your ideas, feedback and criticism. It is intended to supplement the Future of Clean Heat bill and Clean Heat Standard

Clean Heat How homes get to net zero carbon and save \$2,500 a year Solar panels

Heat pump provides heat at 3x the efficiency of furnace. Also provides AC efficiently

Existing furnace remains, but is only used as back up

Solar panels (or CSS) produce enough electricity to power heat pump and all other needs at 25% of the cost of utility electricity

Thick insulation in attic, ceiling of basement and walls reduce energy use 20-30%

Existing stove remains, if gas

An average house needs a 13kW array to reach net zero on its heat-pump heating, all other electricity needs and to charge an EV. This fits on the average roof.

Key benefits of SMCH

- MA cuts CO2 emissions from homes to net zero by 2050¹
- By replacing AC units (not furnaces) with heat pumps, and adding solar panels and insulation, the avg. home saves \$2,500 per year²
 - This cost saving translates to about a \$50,000 increase in house price⁹
 - Even including the financing costs with Mass. Community Climate Bank loans (i.e., no cash down for the homeowner) adding both heat pumps and solar panels cut costs by \$111/month for the average home in MA³
 - Low-income households (mainly tenants) on discounted electricity can save money by heating with a heat pump even without adding solar panels
 - Tenants can add window heat pumps (subsidized by IRA) to replace AC units
- No one must remove their gas furnace (leaving cheap heat even in bitterly-cold winters) or gas stove (making allies of cooks)
- Most of the cost of insulation⁴, heat pumps⁵ and solar panels⁶ is covered by the IRA, MassSave, SMART and net metering
- Low or zero interest-rate loans provided by MassSave Heat Loan and MA Community Climate Bank means no cash up front³
- No new taxes required
- Need "Clean Heat Concierges" to guide people

1 etc. see numbered appendices for supporting data and analysis

Key Elements of SMCH Cut Cost, Cut Carbon, Cut Complexity

<u>MassSave</u>

- Triple scale to 75,000 homes p.a.
- Triple scope to include solar and heat pumps
- Add in IRA incentives allows tripling on current MA budget
- Shift cost from electricity to fossil fuels to incentivize heat pumps (and EVs)
- Need concierges to help people through it all
- Low (or zero) interest rate financing means no cash upfront

Heating

- Require all new AC units to be heat pumps
 - With IRA and MassSave subsidies heat pumps are cheaper than new AC units.
 - All current AC units will need to be replaced by 2050
 - 60% of homes have window AC, 20% central
 - MassSave subsidy to apply to window heat pumps
- Keep current furnace (as back up) and gas stove

<u>IRA</u>

- Add IRA subsidies to MassSave ones
- Cap at current MassSave subsidy
- Limit total subsidy by income according to IRA rules
- Allows MassSave to triple on current budget

Electricity

- Solar, solar, solar
- New time-of-use tariff
- Smart metering to apply discounts to heat pump and EV usage, not entire bill
- Existing low-income discounts (up to 50%) already make heat pumps cheaper than natural gas
- EV saves \$1,500 a year on solar

All 2m MA homes get to net zero by 2050 and save \$2,500 per year on average

Additional Elements of SMCH

Electricity:

- Simplify and expedite the grid interconnection process for rooftop solar
- Expand community-sourced solar (CSS) to allow tenants, homeowners with tiles or shingles, and those with shady roofs to benefit from cheap, clean solar
- Allow neighborhood associations, towns, schools, MLPs, big box stores and utilities to add CSS
- Require a time-of-use electric tariff for night-time EV charging / laundry
 - This reduces the strain on the grid and reduces the use of expensive peaker plants
- Increase R3 discount for heat pumps/electric heating (Unitil just increased the winter-time discount to 6c from the 0.6c currently offered by Eversource), add new discounted rate for EVs
- Use smart metering to apply discounted rates only to heat pump or EV usage, not entire bill
- Allow rolling 20 mins curtailment during peak demand, in return for 20-30% discount (already in TX and CA)

Utilities:

- Require utilities to plan for phase down of gas / phase up of electricity:
 - no stranded assets (i.e. pipes that are no longer needed). DPU to order "repair" vs. "replacement" of pipes; right to "heat" not right to "gas"; must consult with communities
- MassSave to be run by new public authority (to avoid conflicts and IRA denial)

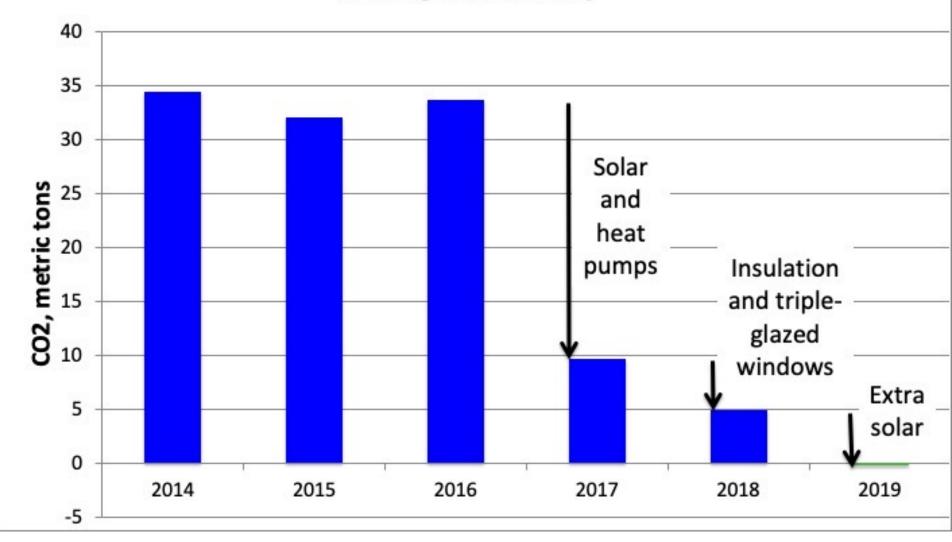

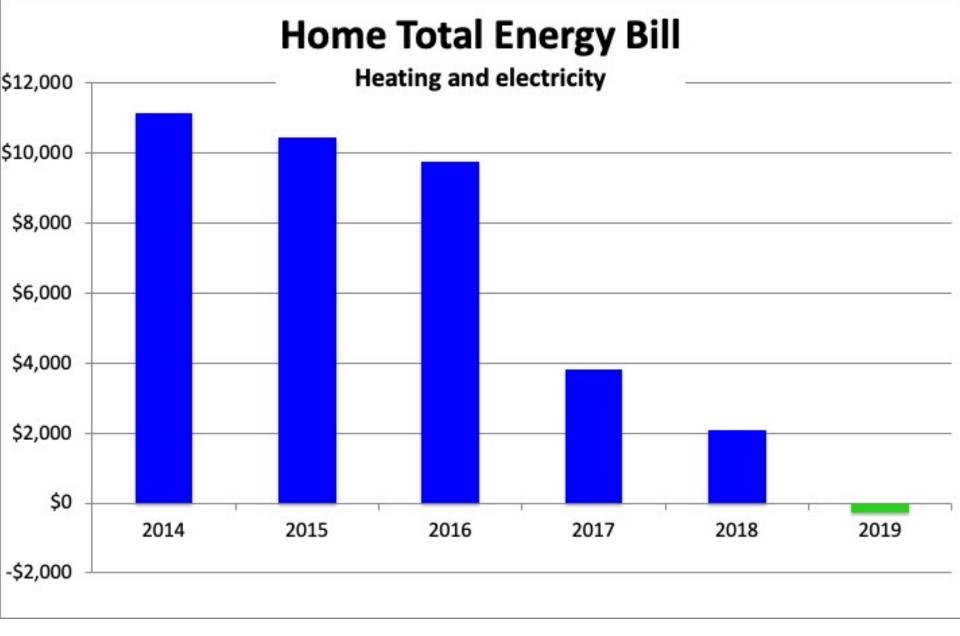

Appendix 1 : Case Study showing net zero energy and net zero bills are possible.

Home Carbon Footprint

Heating and electricity

5,400 sf home in Dover, MA built in 1974, oil heat. 35 other homes from 1,200 sf slab-on-grade to 14,000sf mansions from brand new to 1810 colonial farmhouses have had similar results.

Both carbon emissions and bills were cut to net zero. Total investment (net of subsidies) was \$75,000. Return on investment was 15% after tax.

Zero Carbon Case Study Summary

Total

carhan

					carbon
	Total money				footprint
	invested	Total	Years to	Return on	reduction
	(after subsidies	Money	pay for	Investment	(CO2 per
	and tax credits)	Saved	itself	(after tax)	year)
Heat pumps	\$26,250	\$2,888	9.1	9%	20 Tons
Insulation	\$1,000	\$2,923	0.3	100%	7 Tons
Triple windows	\$4,500	\$974	4.6	19%	2 Tons
Solar panels	\$42,791	\$5 <i>,</i> 572	7.7	13%	14 Tons
Total	\$74 <i>,</i> 541	\$12 <i>,</i> 358	6.0	15%	43 Tons

This homeowner achieved net zero carbon, net zero bills; could have financed all of it with the Heat Loan and Mass Community Climate Bank loans; and paid off the loans with the energy-bill savings before the loans were due.

Please note: a green cell indicates a good financial investment, a red cell indicates a poor one, or at least one where the non-cash benefits such as reducing asthma and carbon emissions should be considered as well as the financial benefits. * Some families may not have the cash available to invest in a CD even after using the 0% Heat Loan and so may not be able to take advantage of the CD interest. If this is the case for you, then eliminate the savings on this line.

Appendix 6: Estimated cost and savings for solar panels on the average 1,800sf house in MA

This array generates enough electricity to get to net zero while heating with a heat pump. To get to net zero on the house and charging an EV, add another 3kW to the array.

A heat-pump hot-water tank requires another 1kW, total 13kW which will fit on an average roof.

Solar Panel FINANCIAL estimates WITHOUT battery					
9 kW array	generates appro>	10,170 kWł	n/year		
	Gross installed cos	t, array only	\$26,236

Save Money

Clean Heat Appendix 7: Estimated cost savings for an EV

compared to a gas-powered equivalent car on utility electricity and on rooftop solar panels.

	Tesla Model 3 Long Range RWD	Toyota Camry XLE
List price (Kelly's Blue Book)	\$42,480	\$31,000
Cost of level 2 home charger	\$2,000	
IRA tax credit	\$7,500	\$0
MA MOREV rebate	\$3,500	\$0
Net cost	\$33,480	\$31,000
5-year maintenance	\$1,115	\$1,168
Cost per mile (\$4/gal, 30c/kWh)	\$0.08	\$0.14
Cost per year to drive 12,000 miles	\$900	\$1,714
Cost per mile (solar @ 8c/kWh)	\$0.02	\$0.14
Cost per year to drive 12,000 miles	\$240	\$1,714

The yellow highlight indicates the lowest cost vehicle in each category of: net cost; 5-year maintenance; and cost to drive on either utility electricity or on electricity from solar panels. When powered by roof-top solar panels, the Tesla Model 3 costs about \$1,500 per year (or \$125 per month) less to run than the Toyota Camry XLE. This is on top of the \$2,500 per year savings from adding solar panels and a heat pump for heating the house.

It takes about 8 extras solar panels (3kW) to power an EV doing 12,000 miles per year.

Appendix 8: Does the Solar Array

fit on the Roof?

Does a solar array to get to net zero fit on the roof?						
	average 1,800sf house in MA					
Additional array size needed to generate all electricity used (heat pumps plus house load)	9	kilowatts				
New array electricity produced per year	10,170	kWh per year				
Electricity purchased from utility per year	0	kWh per year				
Electricity purchased from utility per year	\$0	per year				
Panel size	21.0	sf				
Panel power	425	W				
Number of panels needed	20	panels				
Array area needed	422	sf				
Existing roof area (as flat roof)	851	sf				
Existing roof area as half of sloped roof area	595	sf				
Existing roof area as both sides of sloped roof area	1,191	sf				
Array area as % of both sides of sloped roof area	35%					
Panel cost per watt before tax credits and subsidies	\$3.07	per watt DC				
Array cost (before tax credits and subsidies)	\$26,236	Array cost (before tax credits and subsidies)				

A rooftop solar-panel array that generates enough electricity to get the average home in MA to net zero using a heat pump for heating and also powering all other electricity uses (but not including charging an EV) occupies only 35% of the roof area of the house. To get to net zero on the house and one EV travelling 12,000 miles per year requires a 13kW array that would occupy approximately half the roof area.

Appendix 9: Increased House Prices from Reductions in Utility Bills

1. A homeowner who adds solar panels will, on average, see an increase in their house price by about 4.1%. This is from a study by Zillow:

https://www.zillow.com/research/solar-panels-house-sell-more-23798/ This study looked only at the presence or absence of solar panels, it did not look at the size of the solar panel array. Because a bigger array reduces the bills more than a smaller array, a bigger array will increase the house price more than a smaller array. In general (see the reference below), cutting utility bills by \$1 per year leads to a \$20 increase in house price. Using this rule, an array that offsets the entire electric bill (after adding a heat pump) would increase the house price about 7%.

2. In addition, large-scale academic research shows that adding heat pumps also increases house prices by between 4-7% see here:

https://greenzerocarbonhome.com/heat-pumps-increase-your-house-price-4-7/

 Together, adding heat pumps and solar panels can increase the house price between 8-14%. On the average-priced house in MA (\$630,000 in 2024) this is between \$50,000 and \$90,000 in additional benefit to the homeowner.

Save Money with Clean Heat Cut Cost, Cut Carbon, Cut Complexity

The following people have contributed to this draft:

David Green, member State Legislative Team (SLT) of 350.MA, zero-carbon consultant, author of the book *Zero Carbon Home* and "*Zero Carbon, Zero Bills*" webinar. Policy Working Group leader of Heat Smart Alliance (HSA).

Mark Dyen, member of SLT of 350.MA, energy-policy consultant.

- Michael Duclos, member of HSA, former advisor to Governor Baker, Passive House consultant, and HERS rater.
- Marc Breslow, Founder of MCAN and Arlington heat pump coach.
- Utah Nickel, member of the UCCA node of 350.MA.
- Michael Lesser, Chairman of the Energy Committee, Sherborn, MA.

We have incorporated ideas championed by Senator Mike Barrett, Asst. Majority Leader, Chair Joint Committee on Transportation, Utilities and Energy and ideas that originated in the Future of Clean Heat bill and in the Clean Heat Standard.

None of the organizations above has formally endorsed the SMCH draft legislation.

The analyses supporting the main points were performed by David Green who can be contacted at <u>davidlcgreen@gmail.com</u> with any questions, comments, criticism or ideas.
